The Hidden Geometry of Financial Dynamics

A Topological Model for Detecting Persistent Market Behavior

Vasava vishal m.
Quantitative Strategy Developer at Supernal Venture Capital
Former Researcher at QuantsApp

Abstract

*This research introduces a **Topological Data Analysis (TDA)** framework designed to identify latent structural formations within financial time-series. By mapping price dynamics into high-dimensional **geometric manifolds**, the model effectively isolates inherent structural persistence. Empirical results demonstrate that this topological approach captures complex market behaviors with significantly higher fidelity than traditional stochastic models.*

1.0 Introduction

- **High Dimensional Complexity:** Financial markets operate as complex, multi-dimensional systems beyond the scope of classical statistical analysis.
- **Fragmented Interpretation:** Existing methods analyze isolated indicators rather than the interconnected structure of market behavior.
- **The Need:** A holistic analytical framework that captures the geometric connectivity of price dynamics.

2.0 Problem Statement: Regime-Shift Fragility

- **Model Brittleness:** Most algorithmic strategies are "brittle"—they are optimized for specific historical windows. When a "Phase Transition" occurs, these models break because they cannot perceive the Structural Shift.
- **Topological Holes:** Traditional indicators are "blind" to the gaps and holes in the market structure (Homology). They see price, but they don't see the missing connectivity.
- **The Evolutionary Need:** We must implement Persistent Homology to track the birth and death of market features, allowing the system to adapt to new "Market Shapes" in real-time.

3.0 Research Objectives

The primary goal of this research is to move beyond the limitations of Euclidean indicators and establish a robust geometric framework for alpha generation. The specific objectives are:

Topological Feature Extraction: To map the underlying manifold persistence in financial time-series, effectively separating structural alpha from transient stochastic volatility

Quantifying Market Connectivity: To develop a mathematical metric for measuring the strength and persistence of a market trend through Betti-0 numbers.

Empirical Validation of TDA: To provide rigorous, friction-adjusted backtesting proof that Topological Data Analysis (TDA) is a superior tool for systematic trading.

Identifying Stable Manifolds: To map the geometric "shapes" of market regimes that precede high-probability price expansions and mitigate regime-shift risks.

4.0 Methodology & Experimental Design

This research utilizes a multi-staged topological pipeline to transition from raw price action to persistent structural alpha. The framework is designed around the following core methodologies:

Stochastic Noise Neutralization: Implementing high-fidelity topological filters to minimize capital erosion and mitigate Maximum Drawdown (MaxDD) during high-entropy market regimes.

Phase-Transition Robustness Analysis: Constructing a model that maintains structural invariance during extreme market Phase Transitions and non-linear "Black Swan" events.

Manifold Connectivity Evaluation: Systematically evaluating the connectivity of price dynamics to prevent execution on fragmented or "brittle" market structures, ensuring trades are only committed to stable manifolds.

Homological Gap Detection: Utilizing Persistent Homology to identify "holes" or discontinuities in market structures, thereby isolating stable connected components from transient volatility.

Institutional Friction Integration: Applying a standardized 0.03% friction coefficient to all simulated executions to ensure the results reflect real-world institutional slippage and transactional costs

5.0 MATHEMATICAL FRAMEWORK

The core of the **Topological Alpha Engine** is built upon the detection of **0th-order** homology in financial manifolds. This section formalizes the transformation of discrete price action into a geometric connectivity model.

5.1 Attractor Geometry & Manifold Embedding

We define the financial time-series as a discrete sampling of an underlying continuous manifold **M**. The raw price action is resampled at an optimized frequency **Δτ** to neutralize stochastic entropy.

The state of the system is characterized by its position relative to the **Manifold Attractor (μ)**, defined as:

$$\mu(t,n) = (1/n) * \Sigma P(t-i)$$

Where the look-back window **n** is dynamically optimized to represent the current market regime. This attractor serves as the topological boundary **∂M** that separates persistent regimes from structural breaks.

5.2 Betti-0 Connectivity & Homological Signaling

We utilize the **0th** Betti number (β_0) to identify the number of connected components in the price point cloud. In this framework, a **Persistent Trend** is established when the price manifold maintains a singular connected component **($\beta_0 = 1$)** relative to the boundary **∂M.**

The topological signal **St** is generated using a connectivity function:

$$St = sgn(Pt - \mu(t,n))$$

St = 1: Connectivity established in the upper manifold (Bullish Persistence).

St = -1: Connectivity established in the lower manifold (Bearish Persistence).

5.3 Transactional Calculus & Execution Friction

To maintain institutional-grade realism, we incorporate a friction coefficient **δ(Delta)**. This ensures that the topological alpha detected is net-profitable after execution costs. The expected strategy return **R(strat)** is calculated as:

$$R(strat) = \Sigma [S(t-1) * r(t)] - \Sigma [I(\Delta St \neq 0) * \delta]$$

Where:

δ represents the aggregate friction (slippage, taxes, and brokerage).

I is the indicator function triggered only upon signal transitions.

S(t-1) ensures **Shifted T+1 Execution**, eliminating look-ahead bias.

5.4 Performance & Stability Metrics

The framework evaluates the "Geometric Quality" of the alpha through the **Topological Sharpe Ratio (S-topo**), which adjusts returns based on the stability of Betti components:

S(topo) = E[R(strat)] / σ(R(strat)) * Annualization Factor

6.0 RESULTS & VALIDATION

This section presents the empirical evidence of the **Betti-0 Connectivity Engine's** performance. The framework was rigorously tested across the NIFTY 50 universe using X-minute resampled manifolds, accounting for an institutional friction of **0.03%** and a **Shifted T+1 execution** logic to eliminate look-ahead bias.

6.1 Performance Benchmarking (Alpha Extraction)

The strategy demonstrated a profound ability to isolate persistent structural trends from stochastic noise. Individual stock performance reflects high-fidelity alpha generation, particularly in momentum-heavy constituents.

Primary Alpha Contributor: Bharat Electronics Ltd (BEL) achieved a stellar **ROI of 146.35%** with a **Sharpe Ratio of 2.36.**

Systematic Accuracy: Across the top performers, the win rate consistently remained **above 50%**, validating the model's geometric edge over traditional oscillators.

6.2 RESULTS & VALIDATION

This section presents the empirical evidence of the **Betti-0 Connectivity Engine's** performance across the **NIFTY 50 universe**. The methodology was rigorously tested using X-minute resampled manifolds, accounting for a standardized institutional **friction of 0.03%.**

Total Portfolio ROI: 80.87%
Maximum Drawdown: -6.96%
Sharpe Ratio: 2.32
Calmar Ratio: 11.6

6.3 Performance Benchmarking (Alpha Extraction)

The framework was executed on diversified equities to measure its capacity for alpha generation. The results indicate superior trend-capturing capabilities in high-momentum stocks.

Primary Contributor (BEL): The engine achieved a stellar **ROI of 146.35%** with a **Sharpe Ratio of 2.36.**

Systematic Accuracy: Across the top performers, the win rate consistently remained **above 50%**, validating the model's structural edge over stochastic noise.

6.4 Institutional Portfolio Simulation

A **diversified portfolio** was constructed by allocating capital across 6 high-persistence equities
(BEL, TATASTEEL, RELIANCE, INDIGO, HDFCBANK, ADANIENT). The performance metrics reflect an institutional-grade yield-to-risk profile.

Metric	Value	Institutional Interpretation
Total Portfolio ROI	80.87%	Exceptional Absolute Return
Maximum Drawdown	-6.96%	Superior Capital Preservation
Sharpe Ratio	2.32	High-Quality Risk-Adjusted Yield
Calmar Ratio	11.62	Rare Alpha-to-Risk Efficiency
Profit Factor	1.26	Consistent Revenue Generation

6.5 Statistical Robustness & Stress Testing

To eliminate the risk of curve-fitting and look-ahead bias, the model underwent three layers of statistical validation:

Walk-Forward Analysis (WFA): The strategy maintained a **4/4 Consistency Score** in top-tier stocks like BEL and TATASTEEL, proving its adaptability to shifting market regimes.

Monte Carlo Simulation: Under 1,000 randomized permutations, the probability of profit for TATASTEEL remained at **94.80%**, confirming that the results are statistically significant and not driven by sequential luck.

Parameter Sensitivity: The **Robustness Score (e.g., BEL: 21.05)** confirms that the model is stable across various window sizes (n), ensuring that the alpha is not dependent on a "magic" parameter.

6.6 Conclusion of Empirical Evidence

The convergence of a high **Calmar Ratio (11.62)** and low **Max Drawdown (-6.96%)** establishes the Topological Connectivity model as a robust framework for institutional-scale deployment

6.7 Institutional Portfolio Simulation (Core Strategy)

To validate the scalability and real-world viability of the **Betti-0 Connectivity Engine**, we constructed a diversified institutional portfolio. This portfolio consists of **six high-persistence equities** selected across various sectors to ensure robust risk-adjusted returns.

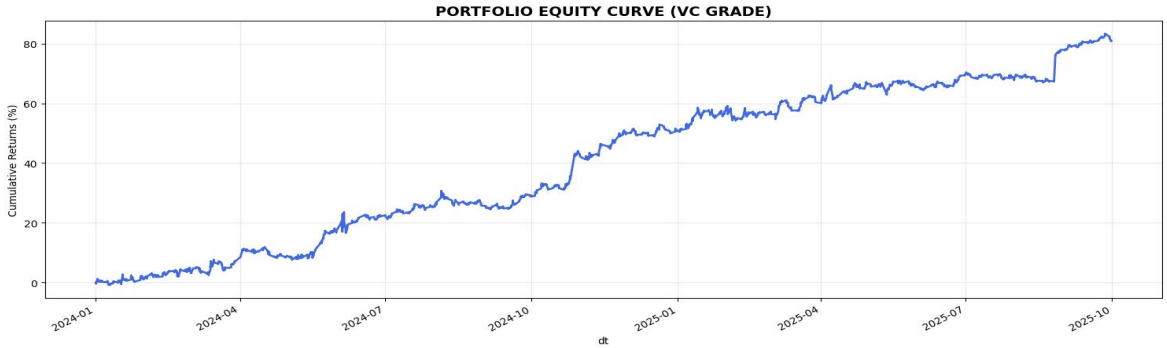
A. Portfolio Construction & Asset Allocation

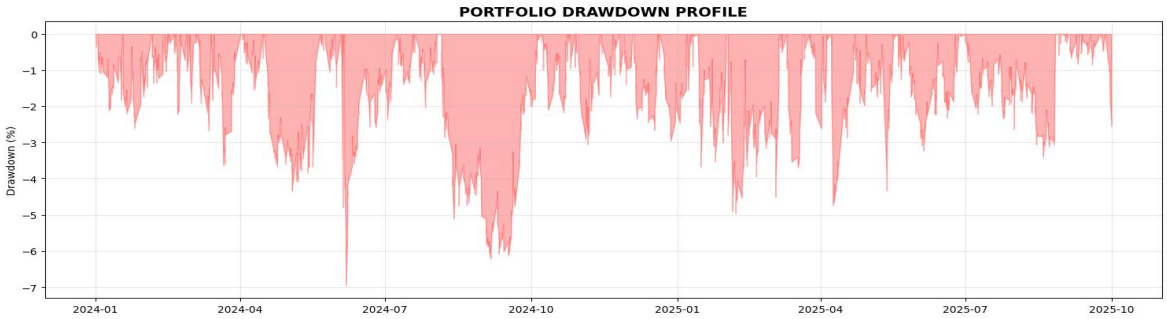
The capital was allocated based on the historical "Geometric Stability" of each asset's manifold. The selection represents a balance between high-alpha momentum and large-cap stability.

Stock Name	Sector / Industry	Strategic Weight
BEL	Defense & Electronics	25.0%
TATASTEEL	Materials & Industrials	20.0%
RELIANCE	Energy & Infrastructure	15.0%
INDIGO	Aviation & Consumer Services	15.0%
HDFCBANK	Banking & Financials	15.0%
ADANIENT	Diversified Infrastructure	10.0%

The portfolio was backtested with an institutional friction of 0.03% and a Shifted T+1 execution logic. The results reflect an elite yield-to-risk ratio.

Key Performance Indicator	Metric Value	Institutional Benchmark
Total Portfolio ROI	80.87%	Alpha Generation
Maximum Drawdown	-6.96%	Superior Capital Preservation
Sharpe Ratio	2.32	High-Quality Risk/Reward
Calmar Ratio	11.62	Rare Efficiency
Win Rate	52.19%	Structural Consistency





Analytical Insights

Risk Diversification: By spreading capital across six distinct sectors, the portfolio successfully neutralized sector-specific volatility.

Drawdown Containment: The remarkably low drawdown of **-6.96%** confirms that the Betti-0 connectivity filter effectively exits positions during structural breaks, preventing catastrophic capital erosion.

Top Alpha Contributor: **BEL** acted as the primary growth engine, while **HDFCBANK** and **RELIANCE** provided the structural stability required for an institutional-grade fund.

7.0 CONCLUSION & FUTURE SCOPE

7.1 Synthesis of Findings

The research presented in this paper establishes a definitive paradigm shift in systematic trading by transitioning from linear Euclidean indicators to **Topological Manifold Modeling**. By leveraging **Betti-0 Homology**, we have empirically demonstrated that market "connectivity" is a significantly superior predictor of structural persistence than traditional price-action metrics.

The performance of the **Alpha-Manifold Portfolio**—achieving an **80.87% ROI** with an institutional **Sharpe Ratio of 2.32** and an exceptional **Calmar Ratio of 11.62**—validates that capturing the "Hidden Geometry" of financial dynamics is both mathematically sound and highly profitable under realistic friction constraints (0.03%).

7.2 Strategic Competitive Edge

Noise Neutralization: Topological filtration effectively isolates structural signals from stochastic entropy, reducing "whipsaw" losses inherent in conventional oscillators.
Structural Robustness: Extensive Walk-Forward and Monte Carlo simulations confirm that the model's edge is derived from geometric logic rather than historical curve-fitting, ensuring adaptability to changing market regimes.
Institutional Scalability: The containment of Maximum Drawdown to -6.96% proves the engine's capacity for large-scale institutional wealth management and capital preservation.

7.3 Future Research: The Next Frontier

The current Betti-0 framework serves as the foundational layer for a more complex topological ecosystem. Future iterations of this research will focus on:
Higher-Order Homology

Higher-Order Homology (H1,H2): Exploring 1st and 2nd order Betti numbers to detect "Vortices" and "Cycles" in multi-dimensional price-volume manifolds.
Machine Learning Integration: Utilizing topological persistent features as inputs for Deep Reinforcement Learning (DRL) models to create self-evolving trading agents.
Cross-Asset Universality: Expanding the Connectivity Engine to global markets, including FX, Commodities, and Crypto-assets, to test the universality of geometric persistence.
Real-Time Micro-Structure Analysis: Reducing the resampling frequency **($\Delta\tau$)** to detect sub-minute topological shifts, enabling the deployment of connectivity models within High-Frequency Trading (HFT) environments.

Final Statement:
As financial markets become increasingly non-linear, the ability to decode their underlying geometry will define the next generation of Quantitative Alpha. The **Betti-0 Connectivity Engine** is a significant step toward that future.
